PREFACE

THE REAL PROPERTY OF

New Joyne

Ĵ.

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D. C. 20314. The purpose of a Phase I investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation and analyses involving topograhic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established guidelines, the spillway design flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. The spillway design flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition, and the downstream damage potential.

PHASE I INSPECTION REPORT NATIONAL DAM INSPECTION PROGRAM

ABSTRACT

Findley Run

Findley Run Dam: NDI I.D. No. PA-00286

<u>Owner</u>:

Nineveh Water Company, subsidiary of the Pennsylvania Electric Company

Pennsylvania (PennDER I.D. No. 32-43)

State Located:

County Located: Indiana

Stream:

Inspection Date: 4 and 21 February 1980

Inspection Team:

GAI Consultants, Inc. 570 Beatty Road Monroeville, Pennsylvania 15146

Based on a visual inspection, operational history, and available engineering data, the dam is considered to be in good condition.

The size classification of the facility is small and its hazard classification is considered to be high. In accordance with the recommended guidelines, the Spillway Design Flood (SDF) for the facility ranges between the 1/2-PMF (Probable Maximum Flood) and the PMF. Due to the relatively small storage capacity and the unusually stable embankment configuration the SDF for the facility is considered to be the 1/2-PMF. Results of the hydrologic and hydraulic analysis indicate the facility is capable of passing and/or storing a flood of 1/2-PMF magnitude. Consequently, the spillway is considered adequate.

> It is recommended that the owner:

Chat Develop a formal emergency warning system to notify downstream residents should hazardous conditions develop. Included in the plan should be provisions for around-theclock surveillance of the facility during periods of unusually heavy precipitation.

b. Observe the cracking in the spillway overflow wall and outlet conduit headwall in future inspections and take remedial measures if necessary.

cont. c Develop formal manuals of operation and maintenance to ensure the continued proper care of the facility. GAI Consultants, Inc. Approved by: Bernard M. Mihalcin, AMES W. PHASE I INSPECTION REPORT NATIONAL DAM INSPECTION PROGRAM FINDLEY RUN DAM NDI# PA-00286, PENNDER #32-43

SECTION 1 GENERAL INFORMATION

1.0 Authority.

The Dam Inspection Act, Public Law 92-367, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a program of inspection of dams throughout the United States.

1.1 Purpose.

The purpose is to determine if the dam constitutes a hazard to human life or property.

1.2 Description of Project

a. Dam and Appurtenances. Findley Run Dam is a 31foot high earth embankment approximately 380 feet long, including spillway. The facility is constructed with a 2stage, reinforced concrete spillway, accommodating both direct and side channel flow located at the left abutment. The service weir is set at elevation 1507.3 feet and has a crest length of 20 feet. The emergency weir is set at elevation 1507.8 feet with a total crest length of 155 feet. Drawdown capacity is provided by a 4- by 6-foot concrete box culvert located about 150 feet from the right abutment. Flow through the culvert is controlled by a sluice gate located at its inlet end and manually operated from the deck of a footbridge that provides access to the mechanism from the embankment crest.

b. Location. Findley Run Dam is located on Findley Run in East Wheatfield Township, Indiana County, Pennsylvania. The site is located about 1.2 miles east of the community of Cramer, Pennsylvania, just off Pennsylvania Route 403. The dam, reservoir and watershed are contained within the Vintondale, Pennsylvania 7.5 minute U.S.G.S. topographic quadrangle (see Figure 1, Appendix E). The coordinates of the dam are N40° 25.3' and W78° 58.4'.

c. <u>Size Classification</u>. Small (31 feet high, 86 acrefeet storage capacity at top of dam).

d. <u>Hazard Classification</u>. High (see Section 3.1.e).

e. <u>Ownership</u>. Nineveh Water Company subsidiary of Pennsylvania Electric Company 1001 Broad Street Johnstown, Pennsylvania 15907

f. Purpose. Domestic and industrial water supply.

g. <u>Historical Data</u>. Findley Run Dam was constructed in 1925-1926 by the Findley Run Water Supply Company of Johnstown, Pennsylvania. The purpose of the facility was to supply domestic water to the mining villages of Cramer and Charles and industrial water to nearby mines in East Wheatfield Township. By 1929, the growing local power industry acquired the dam to supply water to its generating station at Seward. The facility is now owned by the Nineveh Water Company, a wholly owned subsidiary of the Pennsylvania Electric Company (Penelec).

Available state inspection reports contained in PennDER files reveals the facility has been adequately maintained and generally in good condition throughout its history. Minor seepage at various points across the downstream toe was consistently reported; however, no significant deficiencies were recorded.

In July 1977, the dam was overtopped by floodwaters resulting from torrential overnight rains. The watershed experienced intense rainfall reported to be approximately 11 inches in slightly more than 6 hours. The downstream embankment slope was extensively scoured; however, the dam did not fail (see Figure 2). Repairs to the facility were initiated immediately. Included were repairs to the downstream embankment slope (see Figure 3) and the design and construction of a new spillway (see Figures 4, 5 and 6). D'Appolonia Consulting Engineers, Inc., of Pittsburgh, Pennsylvania, served as project consultants for the remedial spillway work which was eventually completed in December 1979.

1.3 Pertinent Data

4.,

a. Drainage Area (square miles). 4.4

b. <u>Discharge at Dam Site</u>.

Discharge Capacity of Outlet Conduit - Discharge curves are not available.

Discharge Capacity of Spillway at Maximum Pool ≈ 11,050 cfs (see Appendix D, Sheet 7).

ć

*

.............

c. Elevation (feet above mean sea level). The following elevations were obtained from available drawings and through field measurements based on the elevation of the top of the right spillway wingwall at 1516.5 feet (see Appendix D, Sheet 1).

	Top of Dam	1515.0 (design). 1515.2 (field).
	Maximum Pool of Record	1516.0 (estimate July 1977).
	Normal Pool	1507.3
	Service Spillway Crest	1507.3
	Emergency Spillway Crest	1507.8
	Upstream Inlet Invert	1486.0
	Downstream Outlet Invert	1484.0 (field).
	Streambed at Dam Centerline	
	Maximum Tailwater	Not Known.
d.	Reservoir Length (feet).	
	Top of Dam	1600
	Normal Pool	1000
e.	Storage (acre-feet).	
	Top of Dam	86
	Normal Pool	45
f.	Reservoir Surface (acres).

SECTION 2 ENGINEERING DATA

2.1 Design.

a. <u>Design Data Availability and Sources</u>. No formal design reports or calculations are available for any aspect of the original facility. Design drawings and miscellaneous design data are contained in PennDER files.

Design information pertaining to the reconstructed facility is available from both the owner and the PennDER. No formal design reports were obtained for review by the inspection team; however, available design information included hydrology data, spillway design calculations, design drawings and contract specifications.

b. Design Features.

1. Embankment. Available data indicate that the original embankment was constructed as a homogeneous earth structure. The embankment material was reported spread in layers not over 6 inches thick, sprinkled and rolled. A clay puddle cutoff trench was reportedly placed along the centerline.

After the damaging flood of 1977, the owner reconstructed the embankment essentially to its original configuration, but, with internal modifications. Figure 3 shows the inclusion of sand drains into the downstream embankment section. Subsequently, excess material (primarily hard sandstone) excavated to accommodate the new spillway was placed along the downstream embankment toe to both sides of the outlet conduit. The upstream embankment face is sloped at 3H:1V and is covered with a 3-foot thick layer of rock riprap. The riprap has been covered, to the left of the footbridge, by a thin layer of earth material that was mistakenly placed by the reconstruction contractor. The crest varies in width from 22 feet (above the outlet conduit) to approximately 200 feet (near spillway) where excess materials were placed. As a consequence, the downstream slope varies widely but, measures roughly 2.5H:lv at the minimum embankment section located at the outlet. The present configuration of the embankment is roughly depicted on the field sketch (General Plan-Field Inspection Notes) contained in Appendix A.

2. Appurtenant Structures.

a) Spillway. The recently renovated spillway

A State of Same

is an uncontrolled, 2-stage, reinforced concrete structure that accommodates a combination of direct and side channel flow. A sharp-crested, L-shaped overflow weir affords a combined crest length of 175 feet (see Figures 4 and 6). A 20-foot long section on the short leg of the L-shape is set at elevation 1507.3 feet and comprises the service overflow. The elevation of the remainder of the L-shape comprising the emergency overflow is 1507.8 feet. The emergency spillway weir is 8.7 feet below the top of the spillway channel wingwalls.

b) Outlet Conduit. The outlet conduit consists of a 4- by 6-foot concrete box culvert located about 150 feet left of the right abutment. Flow through the culvert is manually regulated by a slide gate at its inlet end. The culvert is vented at several locations (see Photograph 3).

c. Specific Design Data and Criteria.

1. Hydrology and Hydraulics. Calculations pertaining to the design of the present spillway facility, by D'Appolonia Engineers, are contained in PennDER files. The design flood hydrograph was computed by use of the U.S. Army Corps of Engineers, HEC-1 Computer Program. Included as input to the program were Snyder unit hydrograph coefficients derived from an HEC-1 runoff hydrograph, which was developed using SCS dimensionless unitgraph and runoff criteria. The peak PMF reservoir inflow computed by this method was about 20,000 cfs. As the selected project design flood ranged from the 100-year frequency to the 1/2-PMF, the spillway was designed to pass discharges in excess of the 1/2-PMF.

2. Embankment. The embankment was reconstructed with the intent of restoring it to essentially its original configuration. Excavation for the new spillway yielded excess materials (primarily rock) which were conveniently placed along the downstream embankment slope, thus, altering its cross section. No formal design data are available.

3. <u>Appurtenant Structures</u>. A complete set of spillway design calculations is contained in PennDER files.

No information is available pertaining to the design of the outlet conduit.

2.2 Construction Records.

Design drawings, contract specifications, several construction photographs and construction progress reports are contained in PennDER files.

.

2.3 Operational Records.

Reservoir levels at Findley Run Dam are recorded daily and are available from the owner. No other records are maintained.

2.4 Other Investigations.

In addition to the information compiled by D'Appolonia Consulting Engineers, Inc., relative to the reconstruction of the facility, several brief state inspection reports are contained in PennDER files.

2.5 Evaluation.

The data available are considered adequate to make a reasonable Phase I assessment of the facility.

MARKAGE ...

SECTION 3 VISUAL INSPECTION

3.1 Observations.

a. <u>General</u>. The general appearance of the facility indicates it to be in good condition.

b. Embankment. Observations made during the visual inspection indicate the embankment is in good condition. No evidence of sloughing, seepage, excessive settlement, animal burrows, or signs of maintenance neglect were observed (see Photograph 1). A portion of the riprapped upstream slope has been inadvertently covered with soil during recent remedial work. This condition is not considered significant.

c. Appurtenant Structures.

1. <u>Spillway</u>. The visual inspection revealed the spillway is in good condition. Minor shrinkage cracks and slight leakage at a construction joint were observed in the channel sidewalls but are not considered significant at present (see Photographs 1, 5, 6 and 7).

2. Outlet Conduit. The outlet conduit was observed by the inspection team to be in good condition. Slight leakage through the joints within the conduit was observed. The headwall at the discharge end has deteriorated and is in need of repair (see Photograph 4).

d. <u>Reservoir Area</u>. The general area surrounding the reservoir is composed of steep, heavily forested slopes. No signs of slope distress were observed.

e. <u>Downstream Channel</u>. From the dam, Findley Run flows in an easterly direction through a steep, narrow, wooded valley toward the village of Cramer, Pennsylvania located less than 2 miles downstream. Near Cramer, 4 homes are located sufficiently close to the stream to sustain damage in the event of a complete embankment failure. It is estimated that as many as 12 to 16 persons could be affected within this reach by such an event. Consequently, the hazard classification is considered to be high.

3.2 Evaluation.

The overall condition of the facility is considered good. Deficiencies noted by the inspection team include

general deterioration of the outlet headwall and cracking in the spillway overflow wall. These conditions are not considered significant at this time, but, should be specifically observed and assessed in future inspections.

-

SECTION 4 OPERATIONAL PROCEDURES

4.1 Normal Operating Procedure.

The facility is essentially self-regulating. Excess inflow discharges over the spillway and is directed downstream. Under normal operating conditions the outlet conduit is closed. The supply lines are regulated daily from the intake structure located along the right shore just upstream of the embankment. All outlet control mechanisms are reportedly functional; however, none were operated in the presence of the inspection team. No formal operations manual is available.

4.2 Maintenance of Dam.

The facility is maintained on an unscheduled basis; however, the facility is visited and observed daily. No formal maintenance program outlining specific maintenance procedures is available.

4.3 Maintenance of Operating Facilities.

See Section 4.2 above.

4.4 <u>Warning System</u>.

No formal warning system is in effect; however, the owner's engineering staff is reportedly developing a system at present.

4.5 Evaluation.

No formal operations or maintenance manuals are available, but, are recommended to ensure the continued proper care and maintenance of the facility No formal warning system is in effect, but, reportedly is being developed by the owners' engineering staff.

SECTION 5 HYDROLOGIC/HYDRAULIC EVALUATION

5.1 Design Data.

Calculations pertaining to the design of the present spillway facility, by D'Appolonia Engineers, are contained in PennDER files. The design flood hydrograph was computed by use of the U.S. Army, Corps of Engineers, HEC-1 Computer Program. Included as input to the program were Snyder unit hydrograph coefficients derived from an HEC-1 runoff hydrograph, which was developed using SCS dimensionless unitgraph and runoff criteria. The peak PMF reservoir inflow computed by this method was about 20,000 cfs. As the selected project design flood ranged from the 100-year frequency to the 1/2-PMF, the spillway was designed to pass discharges in excess of the 1/2-PMF.

5.2 Experience Data.

In July 1977, Findley Run Dam experienced intense rainfall reported to be approximately 11 inches in slightly more than 6 hours. The dam was overtopped by an estimated 1-foot of water. The downstream slope was extensively scoured; however, the dam did not fail. Embankment repairs were initiated immediately and a new spillway subsequently constructed to accommodate large floods not unusual to this region.

5.3 Visual Observations.

On the date of inspection, no conditions were observed that would indicate the spillway could not perform satisfactorily during a flood event, within the limits of its design capacity.

5.4 Method of Analysis.

The facility has been analyzed in accordance with the procedures and guidelines established by the U. S. Army, Corps of Engineers, Baltimore District, for Phase I hydrologic and hydraulic evaluations. The analysis has been performed utilizing a modified version of the HEC-1 program developed by the U. S. Army, Corps of Engineers, Hydrologic Engineering Center, Davis, California. Analytical capabilities of the program are briefly outlined in the preface contained in Appendix D.

5.5 Summary of Analysis.

a. <u>Spillway Design Flood (SDF)</u>. In accordance with procedures and guidelines contained in the National Guidelines for Safety Inspection of Dams for Phase I investigations, the Spillway Design Flood (SDF) for Findley Run Dam ranges between the 1/2-PMF (Probable Maximum Flood) and the PMF. This classification is based on the relative size of the dam (small), and the potential hazard of dam failure to downstream developments (high). Due to the relatively small storage capacity and the unusually stable embankment configuration, the SDF for this facility is considered to be the 1/2-PMF.

b. <u>Results of Analysis</u>. Findley Run Dam was evaluated under near normal operating conditions. That is, the reservoir was initially at its normal pool or service spillway elevation of 1507.3 feet, with the spillway weir discharging freely. The outlet conduit was assumed to be non-functional for the purpose of analysis, since the flow capacity of the conduit is not such that it would significantly increase the total discharge capabilities of the facility. The spillway consists of a two-stage front and side channel concrete sharp-crested weir structure which discharges into a rectangular concrete channel. All pertinent engineering calculations relative to the evaluation of this facility are provided in Appendix D.

The overtopping analysis was made using the Modified HEC-1 Computer Program. The reservoir inflow hydrograph was developed using the Snyder unit hydrograph coefficients provided in the D'Appolonia design calculations. The values of these coefficients were derived from a PMP runoff hydrograph which was developed using SCS dimensionless hydrograph and runoff criteria. The analysis indicated that the discharge/storage capacity of Findley Run Dam can accommodate storms in excess of the 1/2-PMF (the SDF), or about 55 percent of the PMF, prior to embankment overtopping (Appendix D, Summary Input/Output Sheets, Sheet C). The peak 1/2-PMF inflow of approximately 10,120 cfs was slightly attenuated by the discharge/storage capabilities of the dam, as the resulting 1/2-PMF peak outflow was about 10,040 cfs (Summary Input/ Output Sheets, Sheets B and C). The maximum water surface level in the reservoir under 1/2-PMF conditions was about 1514.7, or 0.5 feet below the low top of dam elevation of 1515.2 (Summary Input/Output Sheets, Sheet C).

ST. S.

5.6 Spillway Adequacy.

.

1

Since the spillway at Findley Run Dam is capable of discharging the inflow resulting from a storm in excess of 1/2-PMF magnitude, the spillway is considered adequate.

a carena carron datatana

SECTION 6 EVALUATION OF STRUCTURAL INTEGRITY

6.1 Visual Observations.

a. <u>Embankment</u>. Based on visual observations the embankment is in good condition exhibiting no evidence of instability.

b. Appurtenant Structures.

1. <u>Spillway</u>. The spillway is considered to be in good condition. Cracks observed in the side channel wall appear to be shrinkage related and are considered insignificant to the structural integrity of the spillway.

2. <u>Outlet Conduit</u>. The outlet conduit is in good condition exhibiting only minor leakage at construction joints. The headwall is deteriorated and in need of repair.

6.2 Design and Construction Techniques.

Based on available information, the facility (particularly recently renovated portions) appears to have been designed and constructed in accordance with generally accepted modern techniques and practices.

6.3 Past Performance.

Available records indicate the original facility had a history of leakage near the toe and suffered extensive damage from overtopping. Deficiencies and damage were corrected in remedial work performed during 1978-1979. According to discussions with the owner's representative, the facility has since performed satisfactorily.

6.4 Seismic Stability.

The dam is located in Seismic Zone No. 1 and may be subject to minor earthquake induced dynamic forces. As the facility appears well constructed and sufficiently stable, it is believed that it can withstand the expected dynamic forces; however, no calculations and/or investigations were performed to confirm this belief.

15

Markinger .

SECTION 7 ASSESSMENT AND RECOMMENDATIONS FOR REMEDIAL MEASURES

7.1 Dam Assessment.

a. <u>Safety</u>. The visual inspection suggests the facility is well maintained and in good condition.

The size classification of the facility is small and its hazard classification is considered to be high. In accordance with the recommended guidelines, the Spillway Design Flood (SDF) for the facility ranges between the 1/2-PMF (Probable Maximum Flood) and the PMF. Due to the relatively small storage capacity and unusually stable embankment configuration the SDF for the facility is considered to be the 1/2-PMF. Results of the hydrologic and hydraulic analysis indicate the facility is capable of passing and/or storing the 1/2-PMF. Consequently, the spillway is considered adequate.

b. <u>Adequacy of Information</u>. The available data are considered sufficient to make a reasonable Phase I assessment of the facility.

c. <u>Urgency</u>. The recommendations listed below should be implemented immediately.

d. <u>Necessity for Additional Investigations</u>. No additional investigations are currently deemed necessary.

7.2 Recommendations/Remedial Measures.

It is recommended that the owner:

a. Develop a formal emergency warning system to notify downstream residents should hazardous conditions develop. Included in the plan should be provisions for around-theclock surveillance of the facility during periods of unusually heavy precipitation.

b. Observe the cracking in the spillway overflow wall and outlet conduit headwall in future inspections and take remedial measures if necessary.

c. Develop formal manuals of operation and maintenance to ensure the continued proper care of the facility.

RESERVOIR AREA AND DOWNSTREAM CHANNEL

ŧ

والاحتراب كالانتاب فاستغلم فيردك فلك

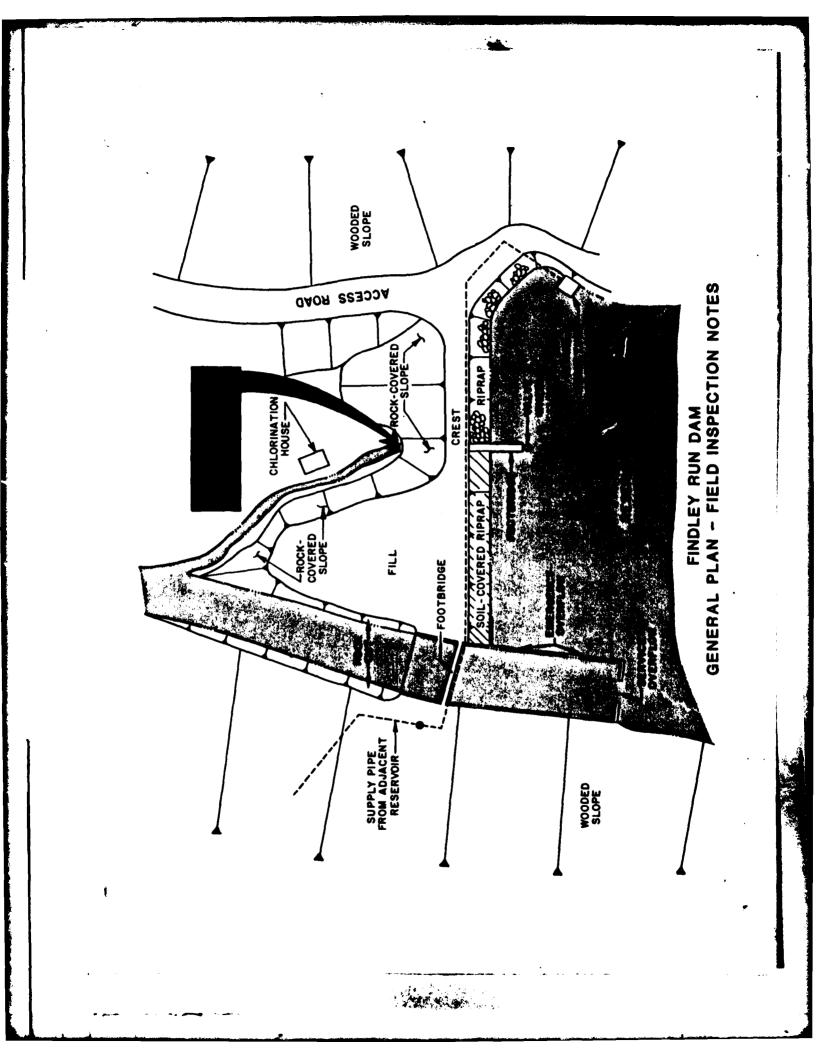

.

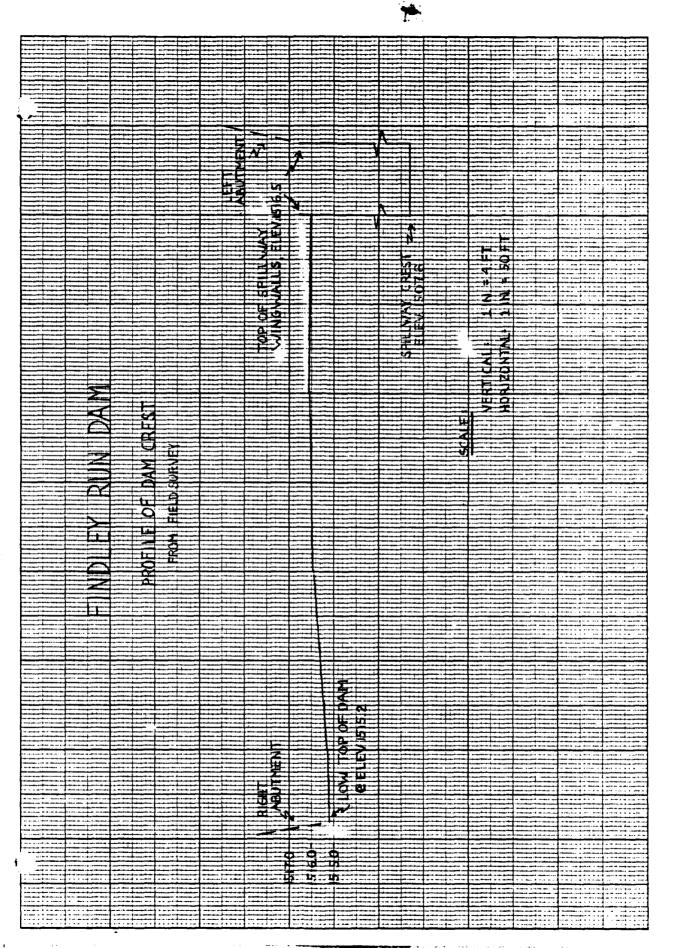

ITEM	OBSERVATIONS/REMARKS/RECOMMENDATIONS NDI# PA· 00286
SLOPES: RESERVOIR	Steep, heavily forested slopes.
SEDIMENTATION	Dredged in 1977. No sedimentation visible.
DOWNSTREAM CHAN- NEL (OBSTRUCTIONS, DEBRIS, ETC.)	Natural channel, unobstructed.
SLOPES: CHANNEL VALLEY	Steep, narrow and wooded valley.
APPROXIMATE NUMBER OF HOMES AND POPULATION	Near Cramer, about 2 miles downstream, 4 homes are located sufficiently near the stream to perhaps sustain damage in the event of an embankment breach. It is estimated that as many as 20 persons could be affected within this reach.

NAME OF DAM Findley Run Dam

i

ŀ

ITEM	REMARKS NDI# PA · 00286
PERSONS INTERVIEWED AND TITLE	Pennsylvania Electric Company R. T. Gallus - Generation Engineering Supervisor.
REGIONAL VICINITY MAP	See Appendix E, Figure 1.
CONSTRUCTION HISTORY	Originally constructed in 1925 - 1926. Overtopped during July 1977 Flood. Extensive repairs completed in 1979 (see Section 1.2.g).
AVAILABLE DRAWINGS	Drawings of original design are contained in PennDER files. Drawings of remedial work performed since July 1977 are available from both the owner and the PennDER.
TYPICAL DAM SECTIONS	See Appendix E, Figure 3.
OUTLETS: PLAN DETAILS DISCHARGE RATINGS	See Appendix E, Figure 4. Discharge curves are not available.

£.,

ITEM	REMARKS NDI# PA · 00286
BORROW SOURCES	From within reservoir and most recently from the area excavated for the new spillway.
POST CONSTRUCTION DAM SURVEYS	None.
POST CONSTRUCTION ENGINEERING STUDIES AND REPORTS	D'Appolonia Consulting Engineers, Inc. of Pittsburgh, Pennsylvania, served as project consultants for the post 1977 reconstruction. No formal reports are available.
HIGH POOL RECORDS	Overtopped in July 1977 by an estimated 1-foot of water. New spillway constructed in late 1979.
MONITORING SYSTEMS	None. Owner plans to install staff gage and possibly piezometers in near future.
MODIFICATIONS	Major remedial work performed since 1977.

A States and a

CHECK LIST ENGINEERING DATA PHASE I (CONTINUED)

ITEM	REMARKS NDI# PA· 00286
PRIOR ACCIDENTS OR FAILURES	Overtopped in July 1977. Extensive damage incurred. Repairs completed in 1979.
MAINTENANCE: RECORDS MANUAL	Maintained as-needed. No formal records or manual are available.
OPERATION: RECORDS MANUAL	Site visited daily. Pool level recorded daily. No formal records or manual are available.
OPERATIONAL PROCEDURES	Self-regulating.
WARNING SYSTEM AND/OR COMMUNICATION FACILITIES	None presently in effect. A system is currently being developed by the owner's engineering staff.

GEOLOGY

Geology.

Findley Run Dam is located in the Allegheny Mountain section of the Appalachian Plateau Province of west central Pennsylvania. In this area, the Allegheny Mountain section is characterized by gently folded sedimentary rock strata of middle Pennsylvanian age. Major structural axes strike from southwest to northeast with flanking strata dipping northwest and southeast.

Structurally, the dam and reservoir lie about one mile southeast of the Ligonier syncline, whose axis strikes in a southwest to northeast regional trend.

The sedimentary rock sequences at the dam site are members of the Allegheny Group of Pennsylvania age. The rocks of this group typically exhibit the rapid vertical and lateral lithologic changes characteristic of cyclic sedimentation. "The Allegheny series is characterized by repeated depositional sequences, some of which locally are complete cyclothems. Shale is the dominate rock type in the section throughout the area, but sandstone is present locally in approximately equal amounts."

Economically, "the Allegheny series in western Pennsylvania contains at least seven economically important coal beds. They are in downward stratigraphic order as follows: Upper Freeport "E", Lower Freeport "D", Upper Kittanning "C Prime", Middle Kittanning "C", Lower Kittaning "B", Clarion "A Prime", and Brookville "A". Only the Upper Freeport, Lower Freeport and Lower Kittanning coals have importance in the New Florence quadrangle and have been exploited commercially. Clay deposits of variable thickness and quality usually underlie the coal beds, as occassionally do argillaceous freshwater limestones. Minor ores of limonite and siderite also are present."

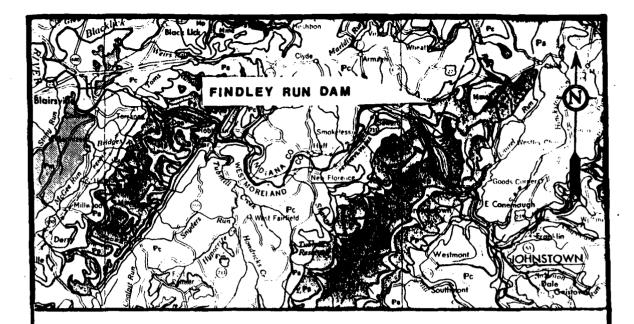

A report contained in PennDER files dated October 10, 1924 discusses, in part, the subsurface conditions at the dam site. "Five diamond drill holes along the centerline of the dam varing in depth from 28 to 70 feet were drilled. These drill holes indicate a depth of from 5 to 16 feet of soil and earth under which is found on the left side of the valley, a layer of conglomerate from 7 to 27 feet thick, under which in turn, are layers of sandstone, conglomerate, slate, clay and thin coal beds. On the right side of the valley, under the surface materials, is found a 9 foot stratum of impure fire clay, under which is 13.5 feet of shale and sandstone."

Commonwealth of Pennsylvania, Department of Forests and Waters, Water and Power Resources Board Permit, File No. 32-43, October 10, 1924.
